

ASSIGNMENT B3

Title: Diffie-Hellman Key Exchange

Problem Statement: Implementation of Diffie-Hellman Key Exchange

Objective:

1 To undertand how Diffie-Hellman key exchange algorithm works 2 Implementation of Diffie-Hellman key exchange

Outcome: Succenfully implemented and undertood Diffie-Hellman key exchange algorithm.

Requirements: python3, jupyter, mpmath

Concepter Related Theory

finite fields. ECC requires a smaller key as compared to non-ECC cryptography to provide equivalent security (a 256-bit ECC security has security equivalent to 3072-bit RSA)

- Elliptic Curve Cryptography (ECC) is an approach to public-key

An elliptic curve is a planar algebraic curve defined by:

y² = x³ + ax + b, where a is the coefficient of x and b is

the constant of the equation. The curve is non-singular, i.e,

its graph has no curps or self-intersections (when the characteristics)

of the coefficient field is equal to 2 or 3).

The Diffie- Hellman algorithm is used to establish a certain shared secret that can be used for secret communications while exchanging data over a public network using the elliptic curve to generate points and get the secret key using the parameters.

Piffie-Kellman (DH) is a simple public-key exchange algorithm for securely exchanging cryptographic keys over a public communication channel. Keys are not actually my exchanged—they are jointly derived. It is named ofter their inventors Whitfield Diffie and Martin Hillman. Note that the public key encryption schemes are only cecure if authenticity of public key is assured.

The protocol enables 2 wers to establish a secret key wing a public key based scheme wing discrete algorithms. The protocol is secure only if the authenticity of the participants can be established.

Alice and Bob agree on a public generator g and prime number p

Alice

Generate a senet (ompute Gompute Generate a secret random number a U=g*modp V=g*modp random number b

Receive V=g*modp

V=g*modp

Gompute sa=V*modp

Gompute sa=V*modp

Shared secret key S=sa=sa=g*modp
